# On a Generalization of Normal, Almost Normal and Mildly Normal Spaces–I

## Erdal Ekici and Takashi Noiri

ABSTRACT. In this paper, we introduce the notions of  $\delta p$ -normal spaces, almost  $\delta p$ -normal spaces, mildly  $\delta p$ -normal spaces,  $g\delta p$ -closed sets and the forms of generalized  $\delta$ -preclosed functions. We obtain characterizations and the relationships of such normal spaces, properties of the forms of generalized  $\delta$ -preclosed functions and preservation theorems.

## 1. INTRODUCTION

Levine [8] initiated the investigation of so-called g-closed sets in topological spaces, since then many modifications of g-closed sets were defined and investigated by a large number of topologists [1, 5, 14]. In 1996, Maki et al. [9] introduced the concepts of gp-closed sets. On the other hand, the notions of p-normal spaces, almost p-normal spaces and mildly p-normal spaces were introduced by Paul and Bhattacharyya [15]; Navalagi [11]; Navalagi [11], respectively.

In this paper we introduce five sections. In the first section, second section and third section, we introduce the notions of  $\delta p$ -normal spaces, almost  $\delta p$ -normal spaces and mildly  $\delta p$ -normal spaces which are the generalized forms of p-normal spaces, almost p-normal spaces and mildly p-normal spaces, respectively. Also, we obtain characterizations and properties of such generalizations of normal spaces. In fourth section, we introduce and study the concepts of  $g\delta p$ -closed sets and some new forms of generalized  $\delta$ -preclosed functions. In the last section, we obtain the relationships between  $\delta p$ -normal spaces and generalized  $\delta$ -preclosed functions.

## 2. Preliminaries

In this paper, spaces always mean topological spaces on which no separation axioms are assumed unless explicitly stated and  $f: (X, \tau) \to (Y, \sigma)$  (or simply  $f: X \to Y$ ) denotes a function f of a space  $(X, \tau)$  into a space  $(Y, \sigma)$ .

Let A be a subset of a space X. The closure and the interior of A are denoted by cl(A) and int(A), respectively.

<sup>2000</sup> Mathematics Subject Classification. Primary: 54D15, 54A05, 54C08.

Key words and phrases.  $\delta p$ -normal space, almost  $\delta p$ -normal space, mildly  $\delta p$ -normal space,  $g\delta p$ -closed set, generalized function.

**Definition 1.** A subset A of a space X is said to be:

(1) regular open [19] if A = int(cl(A)),

(2)  $\alpha$ -open [12] if  $A \subset int(cl(int(A)))$ ,

(3) preopen [10] or nearly open [7] if  $A \subset int(cl(A))$ .

The complement of an  $\alpha$ -open (resp. preopen, regular open) set is called  $\alpha$ -closed [12] (resp. preclosed [10], regular closed [19]). The intersection of all  $\alpha$ -closed (resp. preclosed) sets containing A is called the  $\alpha$ -closure (resp. preclosure) of A and is denoted by  $\alpha$ -cl(A) (resp. pcl(A)). The  $\alpha$ -interior (resp. preinterior) of A, denoted by  $\alpha$ -int(A) (resp. pint(A)) is defined to be the union of all  $\alpha$ -open (resp. preopen) sets contained in A.

The  $\delta$ -interior [20] of a subset A of X is defined by the union of all regular open sets of X contained in A and is denoted by  $\delta$ -int(A). A subset A is called  $\delta$ -open [20] if  $A = \delta$ -int(A), i.e. a set is  $\delta$ -open if it is the union of regular open sets. The complement of a  $\delta$ -open set is called  $\delta$ -closed. Alternatively, a set A of  $(X, \tau)$  is called  $\delta$ -closed [20] if  $A = \delta$ -cl(A), where  $\delta$ -cl $(A) = \{x \in X : A \cap int(cl(U)) \neq \emptyset, U \in \tau \text{ and } x \in U\}$ . A subset A of a space X is said to be  $\delta$ -preopen [16] if  $A \subset int(\delta$ -cl(A)).

The complement of a  $\delta$ -preopen set is said to be  $\delta$ -preclosed. The intersection of all  $\delta$ -preclosed sets of X containing A is called the  $\delta$ -preclosure [16] of A and is denoted by  $\delta$ -pcl(A). The union of all  $\delta$ -preopen sets of X contained in A is called the  $\delta$ -preinterior of A and is denoted by  $\delta$ -pint(A) [16]. A subset U of X is called a  $\delta$ -preneighborhood of a point  $x \in X$  if there exists a  $\delta$ -preopen set V such that  $x \in V \subset U$ . Note that  $\delta$ -pcl(A) = A  $\cup$  cl( $\delta$ -int(A)) and  $\delta$ -pint(A) = A  $\cap$  int( $\delta$ cl(A)).

The family of all  $\delta$ -preopen ( $\delta$ -preclosed,  $\alpha$ -open, regular open, regular closed,  $\delta$ -open,  $\delta$ -closed, preopen) sets of a space X is denoted by  $\delta PO(X)$  (resp.  $\delta PC(X)$ ,  $\alpha O(X)$ , RO(X), RC(X),  $\delta O(X)$ ,  $\delta C(X)$ , PO(X)). The family of all  $\delta$ -preopen sets containing a point x is denoted by  $\delta PO(X, x)$ . It is shown in [13] that  $\alpha O(X)$ is a topology and it is stronger than given topology on X.

**Definition 2.** A space X is said to be prenormal [13] or p-normal [15] if for any pair of disjoint closed sets A and B, there exist disjoint preopen sets U and V such that  $A \subset U$  and  $B \subset V$ .

**Definition 3.** A space X is said to be almost normal [17] (resp. almost p-normal [11]) if for each closed set A and each regular closed set B such that  $A \cap B = \emptyset$ , there exist disjoint open (resp. preopen) sets U and V such that  $A \subset U$  and  $B \subset V$ .

**Definition 4.** A space X is said to be mildly normal [18] (resp. mildly p-normal [11]) if for every pair of disjoint regular closed sets A and B of X, there exist disjoint open (resp. preopen) sets U and V such that  $A \subset U$  and  $B \subset V$ .

**Definition 5.** A function  $f: X \to Y$  is called

- (1) *R*-map [4] if  $f^{-1}(V)$  is regular open in X for every regular open set V of Y,
- (2) completely continuous [2] if  $f^{-1}(V)$  is regular open in X for every open set V of Y.

#### 3. $\delta p$ -normal spaces

**Definition 6.** A space X is said to be  $\delta p$ -normal if for any pair of disjoint closed sets A and B, there exist disjoint  $\delta$ -preopen sets U and V such that  $A \subset U$  and  $B \subset V$ .

**Remark 1.** The following implication holds for a topological space  $(X, \tau)$ :

normal  $\Rightarrow$  p-normal  $\Rightarrow \delta p$ -normal

None of these implications is reversible as shown by the following example.

**Example 1.** Let  $X = \{a, b, c, d\}$  and  $\tau = \{X, \emptyset, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{a, b, c\}, \{a, c, d\}\}$ . Then the space  $(X, \tau)$  is  $\delta p$ -normal but not p-normal.

For the other implication the example can be seen in [13, 15].

**Theorem 1.** For a space X the following are equivalent:

- (1) X is  $\delta p$ -normal,
- (2) for every pair of open sets U and V whose union is X, there exist  $\delta$ -preclosed sets A and B such that  $A \subset U, B \subset V$  and  $A \cup B = X$ ,
- (3) for every closed set F and every open set D containing F, there exists a  $\delta$ -preopen set U such that  $C \subset U \subset \delta$ -pcl(U)  $\subset D$ .

*Proof.* (1)  $\implies$  (2) : Let U and V be a pair of open sets in a  $\delta p$ -normal space X such that  $X = U \cup V$ . Then  $X \setminus U$ ,  $X \setminus V$  are disjoint closed sets. Since X is  $\delta p$ -normal, there exist disjoint  $\delta$ -preopen sets  $U_1$  and  $V_1$  such that  $X \setminus U \subset U_1$  and  $X \setminus V \subset V_1$ . Let  $A = X \setminus U_1$ ,  $B = X \setminus V_1$ . Then A and B are  $\delta$ -preclosed sets such that  $A \subset U$ ,  $B \subset V$  and  $A \cup B = X$ .

(2)  $\implies$  (3): Let C be a closed set and D be an open set containing C. Then  $X \setminus C$  and D are open sets whose union is X. Then by (2), there exist  $\delta$ -preclosed sets  $M_1$  and  $M_2$  such that  $M_1 \subset X \setminus C$  and  $M_2 \subset D$  and  $M_1 \cup M_2 = X$ . Then  $C \subset X \setminus M_1, X \setminus D \subset X \setminus M_2$  and  $(X \setminus M_1) \cap (X \setminus M_2) = \emptyset$ . Let

$$U = X \setminus M_1$$
 and  $V = X \setminus M_2$ .

Then U and V are disjoint  $\delta$ -preopen sets such that  $C \subset U \subset X \setminus V \subset D$ . As  $X \setminus V$  is  $\delta$ -preclosed set, we have  $\delta$ -pcl(U)  $\subset X \setminus V$  and  $C \subset U \subset \delta - pcl(U) \subset D$ .

(3)  $\implies$  (1) : Let  $C_1$  and  $C_2$  be any two disjoint closed sets of X. Put  $D = X \setminus C_2$ , then  $C_2 \cap D = \emptyset$ .  $C_1 \subset D$  where D is an open set. Then by (3), there exists a  $\delta$ -preopen set U of X such that

$$C_1 \subset U \subset \delta - pcl(U) \subset D.$$

It follows that

$$C_2 \subset X \setminus \delta - pcl(U) = V,$$

say, then V is  $\delta$ -preopen and  $U \cap V = \emptyset$ . Hence,  $C_1$  and  $C_2$  are separated by  $\delta$ -preopen sets U and V. Therefore X is  $\delta p$ -normal.

**Definition 7.** A function  $f : X \to Y$  is called strongly  $\delta$ -preopen if  $f(U) \in \delta PO(Y)$  for each  $U \in \delta PO(X)$ .

**Definition 8.** A function  $f : X \to Y$  is called strongly  $\delta$ -preclosed if  $f(U) \in \delta PC(Y)$  for each  $U \in \delta PC(X)$ .

**Theorem 2.** A function  $f : X \to Y$  is strongly  $\delta$ -preclosed if and only if for each subset B in Y and for each  $\delta$ -preopen set U in X containing  $f^{-1}(B)$ , there exists a  $\delta$ -preopen set V containing B such that  $f^{-1}(V) \subset U$ .

*Proof.*  $(\Rightarrow)$ : Suppose that f is strongly  $\delta$ -preclosed. Let B be a subset of Y and  $U \in \delta PO(X)$  containing  $f^{-1}(B)$ . Put  $V = Y \setminus f(X \setminus U)$ , then V is a  $\delta$ -preopen set of Y such that  $B \subset V$  and  $f^{-1}(V) \subset U$ .

 $(\Leftarrow)$ : Let K be any  $\delta$ -preclosed set of X. Then  $f^{-1}(Y \setminus f(K)) \subset X \setminus K$  and  $X \setminus K \in \delta PO(X)$ . There exists a  $\delta$ -preopen set V of Y such that  $Y \setminus f(K) \subset V$  and  $f^{-1}(V) \subset X \setminus K$ . Therefore, we have  $f(K) \supset Y \setminus V$  and  $K \subset f^{-1}(Y \setminus V)$ . Hence, we obtain  $f(K) = Y \setminus V$  and f(K) is  $\delta$ -preclosed in Y. This shows that f is strongly  $\delta$ -preclosed.

**Theorem 3.** If  $f : X \to Y$  is a strongly  $\delta$ -preclosed continuous function from a  $\delta p$ -normal space X onto a space Y, then Y is  $\delta p$ -normal.

Proof. Let  $K_1$  and  $K_2$  be disjoint closed sets in Y. Then  $f^{-1}(K_1)$  and  $f^{-1}(K_2)$ are closed sets. Since X is  $\delta p$ -normal, then there exist disjoint  $\delta$ -preopen sets U and V such that  $f^{-1}(K_1) \subset U$  and  $f^{-1}(K_2) \subset V$ . By the previous theorem, there exist  $\delta$ -preopen sets A and B such that  $K_1 \subset A$ ,  $K_2 \subset B$ ,  $f^{-1}(A) \subset U$  and  $f^{-1}(B) \subset V$ . Also, A and B are disjoint. Thus, Y is  $\delta p$ -normal.  $\Box$ 

**Definition 9.** A function  $f : X \to Y$  is said to be almost  $\delta$ -preirresolute if for each x in X and each  $\delta$ -preneighborhood V of f(x),  $\delta$ -pcl $(f^{-1}(V))$  is a  $\delta$ -preneighborhood of x.

**Lemma 1.** Let  $f: X \to Y$  be a function. Then f is almost  $\delta$ -preirresolute if and only if  $f^{-1}(V) \subset \delta - pint(\delta - pcl(f^{-1}(V)))$  for every  $V \in \delta PO(Y)$ .

**Theorem 4.** A function  $f : X \to Y$  is almost  $\delta$ -preirresolute if and only if  $f(\delta - pcl(U)) \subset \delta - pcl(f(U))$  for every  $U \in \delta PO(X)$ .

Proof.  $(\Rightarrow)$ : Let  $U \in \delta PO(X)$ . Suppose  $y \notin \delta - pcl(f(U))$ . Then there exists  $V \in \delta PO(Y, y)$  such that  $V \cap f(U) = \emptyset$ . Hence  $f^{-1}(V) \cap U = \emptyset$ . Since  $U \in \delta PO(X)$ , we have  $\delta$ -pint $(\delta - pcl(f^{-1}(V))) \cap \delta - pcl(U) = \emptyset$ . Then by Lemma 1,  $f^{-1}(V) \cap \delta - pcl(U) = \emptyset$  and hence  $V \cap f(\delta - pcl(U)) = \emptyset$ . This implies that  $y \notin f(\delta - pcl(U))$ .

 $(\Leftarrow) : \text{If } V \in \delta PO(Y), \text{ then } M = X \setminus \delta - pcl(f^{-1}(V)) \in \delta PO(X). \text{ By hypothesis,} \\ f(\delta - pcl(M)) \subset \delta - pcl(f(M)) \text{ and hence } X \setminus \delta - pint(\delta - pcl(f^{-1}(V))) = \\ \delta - pcl(M) \subset f^{-1}(\delta - pcl(f(M))) \subset f^{-1}(\delta - pcl(f(X \setminus f^{-1}(V)))) \subset f^{-1}(\delta - pcl(Y \setminus V)) \\ = f^{-1}(Y \setminus V) = X \setminus f^{-1}(V). \text{ Therefore }, f^{-1}(V) \subset \delta - pint(\delta - pcl(f^{-1}(V))). \\ \text{By Lemma 1, } f \text{ is almost } \delta \text{-preirresolute.}$ 

**Theorem 5.** If  $f : X \to Y$  is a strongly  $\delta$ -preopen continuous almost  $\delta$ -preirresolute function from a  $\delta$ p-normal space X onto a space Y, then Y is  $\delta$ p-normal.

Proof. Let A be a closed subset of Y and B be an open set containing A. Then by continuity of f,  $f^{-1}(A)$  is closed and  $f^{-1}(B)$  is an open set of X such that  $f^{-1}(A) \subset f^{-1}(B)$ . As X is  $\delta p$ -normal, there exists a  $\delta$ -preopen set U in X such that  $f^{-1}(A) \subset U \subset \delta - pcl(U) \subset f^{-1}(B)$  by Theorem 1. Then,  $f(f^{-1}(A)) \subset$  $f(U) \subset f(\delta - pcl(U)) \subset f(f^{-1}(B))$ . Since f is strongly  $\delta$ -preopen almost  $\delta$ -preirresolute surjection, we obtain  $A \subset f(U) \subset \delta - pcl(f(U)) \subset B$ . Then again by Theorem 1 the space Y is  $\delta p$ -normal.

### 4. Almost $\delta p$ -normal spaces

**Definition 10.** A space X is said to be almost  $\delta p$ -normal if for each closed set A and each regular closed set B such that  $A \cap B = \emptyset$ , there exist disjoint  $\delta$ -preopen sets U and V such that  $A \subset U$  and  $B \subset V$ .

**Remark 2.** The following diagram holds for a topological space  $(X, \tau)$ :

 $\begin{array}{ccc} \operatorname{normal} & \Rightarrow & \operatorname{p-normal} & \Rightarrow & \delta p\operatorname{-normal} \\ & \downarrow & & \downarrow & & \downarrow \\ \operatorname{almost normal} & \Rightarrow & \operatorname{almost} p\operatorname{-normal} & \Rightarrow & \operatorname{almost} \delta p\operatorname{-normal} \end{array}$ 

None of these implications is reversible as shown by the following example.

**Example 2.** Let  $X = \{a, b, c, d\}$  and  $\tau = \{X, \emptyset, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{a, b, c\}, \{a, c, d\}\}$ . Then the space  $(X, \tau)$  is almost  $\delta p$ -normal but not almost p-normal.

For the other implication the example can be seen in the related papers. **Question:** Clearly every  $\delta p$ -normal space is almost  $\delta p$ -normal. Does there exist an almost  $\delta p$ -normal space which is not  $\delta p$ -normal?

**Theorem 6.** For a space X the following statements are equivalent:

- (1) X is almost  $\delta p$ -normal,
- (2) For every pair of sets U and V, one of which is open and the other is regular open whose union is X, there exist  $\delta$ -preclosed sets A and B such that  $A \subset U$ ,  $B \subset V$  and  $A \cup B = X$ ,
- (3) For every closed set A and every regular open set B containing A, there exists a  $\delta$ -preopen set V such that  $A \subset V \subset \delta pcl(V) \subset B$ .

*Proof.* (1)  $\implies$  (2) : Let U be an open set and V be a regular open set in an almost  $\delta p$ -normal space X such that  $U \cup V = X$ . Then  $(X \setminus U)$  is a closed set and  $(X \setminus V)$  is a regular closed set with  $(X \setminus U) \cap (X \setminus V) = \emptyset$ . By almost  $\delta p$ -normality

of X, there exist disjoint  $\delta$ -preopen sets  $U_1$  and  $V_1$  such that  $X \setminus U \subset U_1$  and  $X \setminus V \subset V_1$ . Let  $A = X \setminus U_1$  and  $B = X \setminus V_1$ . Then A and B are  $\delta$ -preclosed sets such that  $A \subset U$ ,  $B \subset V$  and  $A \cup B = X$ .

(2)  $\implies$  (3): Let A be a closed set and B be a regular open set containing A. Then  $X \setminus A$  is open and B is regular open sets whose union is X. Then by (2), there exist  $\delta$ -preclosed sets  $M_1$  and  $M_2$  such that  $M_1 \subset X \setminus A$  and  $M_2 \subset B$  and  $M_1 \cup M_2 = X$ . Then  $A \subset X \setminus M_1$ ,  $X \setminus B \subset X \setminus M_2$  and  $(X \setminus M_1) \cap (X \setminus M_2) = \emptyset$ . Let  $U = X \setminus M_1$  and  $V = X \setminus M_2$ . Then U and V are disjoint  $\delta$ -preopen sets such that  $A \subset U \subset X \setminus V \subset B$ . As  $X \setminus V$  is  $\delta$ -preclosed set, we have  $\delta$ -pcl(U)  $\subset X \setminus V$ and  $A \subset U \subset \delta - pcl(U) \subset B$ .

(3)  $\implies$  (1): Let  $A_1$  and  $A_2$  be any two disjoint closed and regular closed sets, respectively. Put  $D = X \setminus A_2$ , then  $A_2 \cap D = \emptyset$ .  $A_1 \subset D$  where D is a regular open set. Then by (3), there exists a  $\delta$ -preopen set U of X such that  $A_1 \subset U \subset \delta - pcl(U) \subset D$ . It follows that  $A_2 \subset X \setminus \delta - pcl(U) = V$ ,say, then Vis  $\delta$ -preopen and  $U \cap V = \emptyset$ . Hence,  $A_1$  and  $A_2$  are separated by  $\delta$ -preopen sets U and V. Therefore X is almost  $\delta p$ -normal.  $\Box$ 

**Theorem 7.** If  $f : X \to Y$  is a continuous strongly  $\delta$ -preopen R-map and almost  $\delta$ -preirresolute surjection from an almost  $\delta$ p-normal space X onto a space Y, then Y is almost  $\delta$ p-normal.

*Proof.* Similar to Theorem 5.

**Corollary 1.** If  $f : X \to Y$  is a completely continuous strongly  $\delta$ -preopen and almost  $\delta$ -preirresolute surjection from an almost  $\delta$ p-normal space X onto a space Y, then Y is almost  $\delta$ p-normal.

#### 5. Mildly $\delta p$ -normal spaces

**Definition 11.** A space X is said to be mildly  $\delta p$ -normal if for every pair of disjoint regular closed sets A and B of X, there exist disjoint  $\delta$ -preopen sets U and V such that  $A \subset U$  and  $B \subset V$ .

**Remark 3.** The following diagram holds for a topological space  $(X, \tau)$ :

 $\begin{array}{cccc} \operatorname{normal} &\Rightarrow & \operatorname{p-normal} &\Rightarrow & \delta p\operatorname{-normal} \\ & \Downarrow & & \Downarrow & & \Downarrow \\ \operatorname{almost} \operatorname{normal} &\Rightarrow & \operatorname{almost} \operatorname{p-normal} &\Rightarrow & \operatorname{almost} \delta p\operatorname{-normal} \\ & \Downarrow & & \Downarrow & & \Downarrow \\ & & & \Downarrow & & & \Downarrow \\ \operatorname{mildly} \operatorname{normal} &\Rightarrow & \operatorname{mildly} p\operatorname{-normal} &\Rightarrow & \operatorname{mildly} \delta p\operatorname{-normal} \end{array}$ 

**Question:** Clearly every almost  $\delta p$ -normal space is mildly  $\delta p$ -normal. Does there exist a mildly  $\delta p$ -normal (resp. mildly  $\delta p$ -normal) space which is not mildly p-normal (resp. almost  $\delta p$ -normal)?

**Theorem 8.** For a space X the following are equivalent:

(1) X is mildly  $\delta p$ -normal,

- (2) For every pair of regular open sets U and V whose union is X, there exist  $\delta$ -preclosed sets G and H such that  $G \subset U$ ,  $H \subset V$  and  $G \cup H = X$ ,
- (3) For any regular closed set A and every regular open set B containing A, there exists a  $\delta$ -preopen set U such that  $A \subset U \subset \delta - pcl(U) \subset B$ ,
- (4) For every pair of disjoint regular closed sets A and B, there exist  $\delta$ -preopen sets U and V such that  $A \subset U$ ,  $B \subset V$  and  $\delta pcl(U) \cap \delta pcl(V) = \emptyset$ .

*Proof.* Similar to Theorem 1.

**Theorem 9.** If  $f : X \to Y$  is an strongly  $\delta$ -preopen R-map and almost  $\delta$ -preirresolute function from a mildly  $\delta$ p-normal space X onto a space Y, then Y is mildly  $\delta$ p-normal.

*Proof.* Let A be a regular closed set and B be a regular open set containing A. Then by R-map of f,  $f^{-1}(A)$  is a regular closed set contained in the regular open set  $f^{-1}(B)$ . Since X is mildly  $\delta p$ -normal, there exists a  $\delta$ -preopen set V such that

$$f^{-1}(A) \subset V \subset \delta - pcl(V) \subset f^{-1}(B)$$

by Theorem 8. As f is strongly  $\delta$ -preopen and an almost  $\delta$ -preirresolute surjection, it follows that  $f(V) \in \delta PO(Y)$  and  $A \subset f(V) \subset \delta - pcl(f(V)) \subset B$ . Hence Y is mildly  $\delta p$ -normal.

**Theorem 10.** If  $f : X \to Y$  is *R*-map, strongly  $\delta$ -preclosed function from a mildly  $\delta p$ -normal space X onto a space Y, then Y is mildly  $\delta p$ -normal.

*Proof.* Similar to Theorem 3.

### 6. $g\delta p$ -closed sets and generalized functions

**Definition 12.** A subset A of a space  $(X, \tau)$  is said to be g-closed [8] (resp. gpclosed [9]) if  $cl(A) \subset U$  (resp. p- $cl(A) \subset U$ ) whenever  $A \subset U$  and  $U \in \tau$ . The complement of g-closed (resp. gp-closed) set is said to be g-open (resp. gp-open).

**Definition 13.** A subset A of a space  $(X, \tau)$  is said to be  $g\delta p$ -closed if  $\delta$ - $pcl(A) \subset U$  whenever  $A \subset U$  and  $U \in \tau$ . The complement of  $g\delta p$ -closed set is said to be  $g\delta p$ -open.

**Remark 4.** The following diagram holds for any subset of a topological space  $(X, \tau)$ :

$\delta$ -preclosed	$\Rightarrow$	$g\delta p$ -closed
↑		↑
preclosed	$\Rightarrow$	gp-closed
↑		↑
closed		g-closed

None of these implications is reversible as shown by the following examples.

**Example 3.** Let  $X = \{a, b, c, d\}$  and  $\tau = \{X, \emptyset, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{a, b, c\}, \{a, c, d\}\}$ . Then the set  $\{a, d\}$  is  $g\delta p$ -closed but it is not gp-closed. Let  $\tau = \{X, \emptyset, \{b\}, \{d\}, \{b, d\}\}$ . Then the set  $\{b, c\}$  is  $g\delta p$ -closed but it is not  $\delta$ -preclosed.

 $\square$ 

For the other implications the examples can be seen in [3, 9, 10, 16].

**Definition 14.** A function  $f: X \to Y$  is said to be

- (1)  $\delta$ -preclosed if f(K) is  $\delta$ -preclosed in Y for each closed set K of X,
- (2)  $g\delta p$ -closed if f(K) is  $g\delta p$ -closed in Y for each closed set K of X.

**Definition 15.** A function  $f: X \to Y$  is said to be

- (1) quasi  $\delta$ -preclosed if f(K) is closed in Y for each  $K \in \delta PC(X)$ ,
- (2)  $\delta p$ -g $\delta p$ -closed if f(K) is  $g\delta p$ -closed in Y for each  $K \in \delta PC(X)$ ,
- (3) almost  $g\delta p$ -closed if f(K) is  $g\delta p$ -closed in Y for each  $K \in RC(X)$ .

**Remark 5.** The following diagram holds for a function  $f: (X, \tau) \to (Y, \sigma)$ :

 $\begin{array}{ccc} \text{almost } g\delta p\text{-closed} \\ & \uparrow \\ \delta p\text{-}g\delta p\text{-closed} \\ & \uparrow \\ \text{strongly } \delta\text{-preclosed} \\ & \uparrow \\ \text{quasi } \delta\text{-preclosed} \\ & \Rightarrow \\ \end{array}$ 

None of these implications is reversible as shown by the following examples.

**Example 4.** Let  $X = Y = \{a, b, c, d\}$  and  $\tau = \sigma = \{X, \emptyset, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{a, b, c\}, \{a, c, d\}\}$ . Let  $f : (X, \tau) \to (Y, \sigma)$  be a function defined as follows: f(a) = a, f(b) = c, f(c) = c and f(d) = d. Then f is almost  $g\delta p$ -closed but it is not  $g\delta p$ -closed.

If we define the function  $f: (X, \tau) \to (Y, \sigma)$  as follows: f(a) = a, f(b) = a, f(c) = c and f(d) = d, then f is  $\delta$ -preclosed but it is not closed. If we define the function f as follows: f(a) = c, f(b) = a, f(c) = c and f(d) = d, then f is  $\delta$ -preclosed but it is not strongly  $\delta$ -preclosed. If we define the function f as an identity function, then f is closed and strongly  $\delta$ -preclosed but it is not quasi  $\delta$ -preclosed.

**Example 5.** Let  $X = Y = \{a, b, c, d\}$  and  $\tau = \sigma = \{X, \emptyset, \{b\}, \{d\}, \{b, d\}\}$ . Let  $f : (X, \tau) \to (Y, \sigma)$  be a function. If we define the function  $f : (X, \tau) \to (Y, \sigma)$  as follows: f(a) = c, f(b) = d, f(c) = c and f(d) = d, then f is  $\delta p$ - $g\delta p$ -closed but it is not  $\delta p$ - $\delta pg$ -closed. If we define the function f as follows: f(a) = a, f(b) = a, f(c) = d and f(d) = d, then f is  $g\delta p$ -closed but it is neither  $\delta pg$ -closed nor  $\delta p$ - $g\delta p$ -closed.

**Definition 16.** A function  $f: X \to Y$  is said to be  $\delta p$ - $g\delta p$ -continuous if  $f^{-1}(K)$  is  $g\delta p$ -closed in X for every  $K \in \delta PC(Y)$ .

**Theorem 11.** A function  $f: X \to Y$  is  $\delta p$ -g $\delta p$ -continuous if and only if  $f^{-1}(V)$  is g $\delta p$ -open in X for every  $V \in \delta PO(Y)$ .

**Theorem 12.** If  $f : X \to Y$  is closed  $\delta p$ -g $\delta p$ -continuous, then  $f^{-1}(K)$  is g $\delta p$ -closed in X for each g $\delta p$ -closed set K of Y.

*Proof.* Let K be a  $g\delta p$ -closed set of Y and U an open set of X containing  $f^{-1}(K)$ . Put V = Y - f(X - U), then V is open in Y,  $K \subset V$ , and  $f^{-1}(V) \subset U$ . Therefore, we have  $\delta$ - $pcl(K) \subset V$  and hence

$$f^{-1}(K) \subset f^{-1}(\delta - pcl(K)) \subset f^{-1}(V) \subset U.$$

Since f is  $\delta p$ - $g\delta p$ -continuous,  $f^{-1}(\delta - pcl(K))$  is  $g\delta p$ -closed in X and hence  $\delta - pcl(f^{-1}(K)) \subset \delta - pcl(f^{-1}(\delta - pcl(K))) \subset U$ . This shows that  $f^{-1}(K)$  is  $g\delta p$ -closed in X.

**Theorem 13.** A function  $f : X \to Y$  is  $\delta p$ -g $\delta p$ -closed if and only if for each subset B of Y and each  $U \in \delta PO(X)$  containing  $f^{-1}(B)$ , there exists a g $\delta p$ -open set V of Y such that  $B \subset V$  and  $f^{-1}(V) \subset U$ .

*Proof.*  $(\Rightarrow)$  : Suppose that f is  $\delta p$ - $g\delta p$ -closed. Let B be a subset of Y and  $U \in \delta PO(X)$  containing  $f^{-1}(B)$ . Put  $V = Y \setminus f(X \setminus U)$ , then V is a  $g\delta p$ -open set of Y such that  $B \subset V$  and  $f^{-1}(V) \subset U$ .

 $(\Leftarrow)$ : Let K be any  $\delta$ -preclosed set of X. Then  $f^{-1}(Y \setminus f(K)) \subset X \setminus K$  and  $X \setminus K \in \delta PO(X)$ . There exists a  $g\delta p$ -open set V of Y such that  $Y \setminus f(K) \subset V$  and  $f^{-1}(V) \subset X \setminus K$ . Therefore, we have  $f(K) \supset Y \setminus V$  and  $K \subset f^{-1}(Y \setminus V)$ . Hence, we obtain  $f(K) = Y \setminus V$  and f(K) is  $g\delta p$ -closed in Y. This shows that f is  $\delta p$ - $g\delta p$ -closed.

**Theorem 14.** If  $f : X \to Y$  is continuous  $\delta p$ -g $\delta p$ -closed, then f(H) is g $\delta p$ -closed in Y for each g $\delta p$ -closed set H of X.

Proof. Let H be any  $g\delta p$ -closed set of X and V an open set of Y containing f(H). Since  $f^{-1}(V)$  is an open set of X containing H,  $\delta$ - $pcl(H) \subset f^{-1}(V)$  and hence  $f(\delta$ - $pcl(H)) \subset V$ . Since f is  $\delta p$ - $g\delta p$ -closed and  $\delta$ - $pcl(H) \in \delta PC(X)$ , we have  $\delta$ - $pcl(f(H)) \subset \delta$ - $pcl(f(\delta$ - $pcl(H))) \subset V$ . Therefore, f(H) is  $g\delta p$ -closed in Y.  $\Box$ 

**Definition 17.** A function  $f: X \to Y$  is said to be  $\delta$ -preirresolute [6] if  $f^{-1}(V) \in \delta PO(X)$  for every  $V \in \delta PO(Y)$ .

**Remark 6.** A  $\delta$ -preirresolute function is  $\delta p$ - $g\delta p$ -continuous but not conversely.

**Example 6.** Let  $X = Y = \{a, b, c, d\}$  and  $\tau = \sigma = \{X, \emptyset, \{b\}, \{d\}, \{b, d\}\}$ . Let  $f : (X, \tau) \to (Y, \sigma)$  be a function defined as follows: f(a) = b, f(b) = d, f(c) = c and f(d) = d. Then f is  $\delta p$ -g $\delta p$ -continuous but it is not  $\delta$ -preirresolute.

**Corollary 2.** If  $f : X \to Y$  is closed  $\delta$ -preirresolute, then  $f^{-1}(K)$  is  $g\delta p$ -closed in X for each  $g\delta p$ -closed set K of Y.

**Theorem 15.** Let  $f: X \to Y$  and  $g: Y \to Z$  be functions. Then

- (1) the composition  $gof: X \to Z$  is  $\delta p$ -g $\delta p$ -closed if f is  $\delta p$ -g $\delta p$ -closed and g is continuous  $\delta p$ -g $\delta p$ -closed,
- (2) the composition  $gof : X \to Z$  is  $\delta p$ -g $\delta p$ -closed if f is strongly  $\delta$ -preclosed and g is  $\delta p$ -g $\delta p$ -closed,
- (3) the composition  $gof: X \to Z$  is  $\delta p$ -g $\delta p$ -closed if f is quasi  $\delta$ -preclosed and g is  $g\delta p$ -closed.

**Theorem 16.** Let  $f : X \to Y$  and  $g : Y \to Z$  be functions and let the composition  $gof : X \to Z$  be  $\delta p$ -g $\delta p$ -closed. Then, if f is an  $\delta$ -preirresolute surjection, then g is  $\delta p$ -g $\delta p$ -closed.

*Proof.* Let  $K \in \delta PC(Y)$ . Since f is  $\delta$ -preirresolute and surjective,  $f^{-1}(K) \in \delta PC(X)$  and  $(gof)(f^{-1}(K)) = g(K)$ . Therefore, g(K) is  $g\delta p$ -closed in Z and hence g is  $\delta p$ - $g\delta p$ -closed.

**Theorem 17.** Let  $f : X \to Y$  and  $g : Y \to Z$  be functions and let the composition  $gof : X \to Z$  be  $\delta p$ -g $\delta p$ -closed. Then, if g is a closed  $\delta p$ -g $\delta p$ -continuous injection, then f is  $\delta p$ -g $\delta p$ -closed.

Proof. Let  $H \in \delta PC(X)$ . Then (gof)(H) is  $g\delta p$ -closed in Z and  $g^{-1}((gof)(H)) = f(H)$ . By Theorem 12, f(H) is  $g\delta p$ -closed in Y and hence f is  $\delta p$ -g $\delta p$ -closed.  $\Box$ 

7. Further characterizations of  $\delta p$ -normal spaces

**Lemma 2.** A subset A of a space X is  $g\delta p$ -open if and only if  $F \subset \delta$ -pint(A) whenever F is closed and  $F \subset A$ .

**Theorem 18.** For a topological space X, the following are equivalent:

- (a) X is  $\delta p$ -normal,
- (b) for any pair of disjoint closed sets A and B of X, there exist disjoint gδp-open sets U and V of X such that A ⊂ U and B ⊂ V,
- (c) for each closed set A and each open set B containing A, there exists a  $g\delta p$ -open set U such that  $A \subset U \subset \delta$ -pcl $(U) \subset B$ ,
- (d) for each closed set A and each g-open set B containing A, there exists a  $\delta$ -preopen set U such that  $A \subset U \subset \delta$ -pcl(U)  $\subset int(B)$ ,
- (e) for each closed set A and each g-open set B containing A, there exists a  $g\delta p$ -open set G such that  $A \subset G \subset \delta$ - $pcl(G) \subset int(B)$ ,
- (f) for each g-closed set A and each open set B containing A, there exists a  $\delta$ -preopen set U such that  $cl(A) \subset U \subset \delta$ -pcl(U)  $\subset B$ ,
- (g) for each g-closed set A and each open set B containing A, there exists a  $g\delta p$ -open set G such that  $cl(A) \subset G \subset \delta$ - $pcl(G) \subset B$ .

*Proof.*  $(a) \Leftrightarrow (b) \Leftrightarrow (c)$ : Since every  $\delta$ -preopen set is  $g\delta p$ -open, it is obvious.

 $(d) \Rightarrow (e)$  and  $(f) \Rightarrow (g) \Rightarrow (c)$ : Since every closed (resp. open) set is g-closed (resp. g-open), it is obvious.

 $(c) \Rightarrow (d)$ : Let A be any closed subset of X and B be a g-open set containing A. We have  $A \subset int(B)$ . Then there exists a  $g\delta p$ -open set G such that  $A \subset G \subset \delta$ - $pcl(G) \subset int(B)$ . Since G is  $g\delta p$ -open, by Lemma 2  $A \subset \delta$ -pint(G). Put  $U = \delta$ -pint(G), then U is  $\delta$ -preopen and  $A \subset U \subset \delta$ - $pcl(U) \subset int(B)$ .

 $(e) \Rightarrow (f)$ : Let A be any g-closed subset of X and B be an open set containing A. We have  $cl(A) \subset B$ . Then there exists a  $g\delta p$ -open set G such that  $cl(A) \subset G \subset \delta$ - $pcl(G) \subset B$ . Since G is  $g\delta p$ -open and  $cl(A) \subset G$ , by Lemma 2 we have  $cl(A) \subset \delta$ -pint(G), put  $U = \delta$ -pint(G), then U is  $\delta$ -preopen and  $cl(A) \subset U \subset \delta$ - $pcl(U) \subset B$ .

**Theorem 19.** If  $f : X \to Y$  is a continuous quasi  $\delta$ -preclosed surjection and X is  $\delta p$ -normal, then Y is normal.

Proof. Let  $M_1$  and  $M_2$  be any disjoint closed sets of Y. Since f is continuous,  $f^{-1}(M_1)$  and  $f^{-1}(M_2)$  are disjoint closed sets of X. Since X is  $\delta p$ -normal, there exist disjoint  $U_1, U_2 \in \delta PO(X)$  such that  $f^{-1}(M_i) \subset U_i$  for i = 1, 2. Put  $V_i = Y - f(X - U_i)$ , then  $V_i$  is open in  $Y, M_i \subset V_i$  and  $f^{-1}(V_i) \subset U_i$  for i = 1, 2. Since  $U_1 \cap U_2 = \emptyset$  and f is surjective, we have  $V_1 \cap V_2 = \emptyset$ . This shows that Y is normal.

**Theorem 20.** Let  $f : X \to Y$  be a closed  $\delta p$ -g $\delta p$ -continuous injection. If Y is  $\delta p$ -normal, then X is  $\delta p$ -normal.

Proof. Let  $N_1$  and  $N_2$  be disjoint closed sets of X. Since f is a closed injection,  $f(N_1)$  and  $f(N_2)$  are disjoint closed sets of Y. By the  $\delta p$ -normality of Y, there exist disjoint  $V_1, V_2 \in \delta PO(Y)$  such that  $f(N_i) \subset V_i$  for i = 1, 2. Since fis  $\delta p$ -g $\delta p$ -continuous,  $f^{-1}(V_1)$  and  $f^{-1}(V_2)$  are disjoint  $g\delta p$ -open sets of X and  $N_i \subset f^{-1}(V_i)$  for i = 1, 2. Now, put  $U_i = \delta$ -pint $(f^{-1}(V_i))$  for i = 1, 2. Then,  $U_i \in \delta PO(X), N_i \subset U_i$  and  $U_1 \cap U_2 = \emptyset$ . This shows that X is  $\delta p$ -normal.  $\Box$ 

**Corollary 3.** If  $f : X \to Y$  is a closed  $\delta$ -preirresolute injection and Y is  $\delta$ p-normal, then X is  $\delta$ p-normal.

**Lemma 3.** A function  $f : X \to Y$  is almost  $g\delta p$ -closed if and only if for each subset B of Y and each  $U \in RO(X)$  containing  $f^{-1}(B)$ , there exists a  $g\delta p$ -open set V of Y such that  $B \subset V$  and  $f^{-1}(V) \subset U$ .

**Lemma 4.** If  $f: X \to Y$  is almost  $g\delta p$ -closed, then for each closed set M of Y and each  $U \in RO(X)$  containing  $f^{-1}(M)$ , there exists  $V \in \delta PO(Y)$  such that  $M \subset V$  and  $f^{-1}(V) \subset U$ .

**Theorem 21.** Let  $f : X \to Y$  be a continuous almost  $g\delta p$ -closed surjection. If X is normal, then Y is  $\delta p$ -normal.

Proof. Let  $M_1$  and  $M_2$  be any disjoint, closed sets of Y. Since f is continuous,  $f^{-1}(M_1)$  and  $f^{-1}(M_2)$  are disjoint closed sets of X. By the normality of X, there exist disjoint open sets  $U_1$  and  $U_2$  such that  $f^{-1}(M_i) \subset U_i$ , where i = 1, 2. Now, put  $G_i = int(cl(U_i))$  for i = 1, 2, then  $G_i \in RO(X)$ ,  $f^{-1}(M_i) \subset U_i \subset G_i$  and  $G_1 \cap G_2 = \emptyset$ . By Lemma 4, there exists  $V_i \in \delta PO(Y)$  such that  $M_i \subset V_i$  and  $f^{-1}(V_i) \subset G_i$ , where i = 1, 2. Since  $G_1 \cap G_2 = \emptyset$  and f is surjective, we have  $V_1 \cap V_2 = \emptyset$ . This shows that Y is  $\delta p$ -normal.

**Corollary 4.** If  $f : X \to Y$  is a continuous  $\delta$ -preclosed surjection and X is normal, then Y is  $\delta$ p-normal.
