

SCALAR CURVATURE FOR MIDDLE PLANES IN  
ODD-DIMENSIONAL TORSE-FORMING ALMOST RICCI  
SOLITONS

MIRCEA CRASMAREANU<sup>1</sup>

ABSTRACT. We derive identities for the scalar curvature of  $n$  respectively  $(n + 1)$ -dimensional planes and their orthogonal complements in an  $(2n + 1)$ -dimensional torse-forming almost Ricci soliton. If the torse-forming vector field is an eigenvector of the Ricci endomorphism for a special eigenvalue these identities characterize the almost Ricci soliton case.

Let  $(M^m, g)$  be a Riemannian manifold of dimension  $m \geq 2$ . Let  $p \in M$  and the tangent plane  $\pi \subseteq T_p M$  spanned by the orthonormal basis  $\{u, v\} \in T_p M$ . Then the sectional curvature of  $\pi$  is denoted  $K(\pi)$  or  $K(u \wedge v)$ . It represents the Gaussian curvature of the surface:  $(\alpha, \beta) \in \mathbb{R}^2 \rightarrow \exp_p(\alpha u + \beta v) \in M$ . This well-known notion was generalized to arbitrary dimension of the plane sections in [5].

**Definition 1.** Fix  $2 \leq n \leq m$  and  $L \subset T_p M$  a  $n$ -dimensional plane section with the orthonormal basis  $\{e_1, \dots, e_n\}$ . The *scalar curvature* of  $L$  is:

$$(1) \quad \tau(L) := \sum_{1 \leq i < j \leq n} K(e_i \wedge e_j).$$

The Singer-Thorpe characterization of 4-dimensional Einstein spaces from [15] is a duality for the usual sectional curvature:

**Theorem 1.**  $(M^4, g)$  is an Einstein manifold if and only if  $K(\pi) = K(\pi^\perp)$  for any plane section  $\pi$ .

This result was generalized by Chen et. al in [6], see also Proposition 13.1 of [3, p. 254].

**Theorem 2.**  $(M^{2n}, g)$  is Einstein if and only if  $\tau(L) = \tau(L^\perp)$  for any  $n$ -plane section  $L$ .

The odd-dimensional case was obtained in [7].

**Theorem 3.**  $(M^{2n+1}, g)$  is Einstein with the corresponding scalar  $\lambda$  if and only if  $\tau(L) + \frac{\lambda}{2} = \tau(L^\perp)$  for any  $n$ -plane section  $L$ .

The last two results have been generalized in: [1] for quasi-Einstein manifolds, [8] and [16] for generalized quasi-Einstein manifolds, [9] for super quasi-Einstein manifolds, [12] for mixed super quasi-Einstein manifold, [13] for mixed generalized quasi-Einstein manifold and [14] for pseudo generalized quasi-Einstein manifold. A very recent generalization to arbitrary dimension of  $L$  appears in [11].

In this short note we derive a similar result for *almost Ricci solitons* on  $(M^{2n+1}, g)$ , i.e., pairs  $(V, \lambda) \in \mathfrak{X}(M) \times C^\infty(M)$  with  $V$  a given vector field and  $\lambda$  a smooth real function satisfying:

$$(2) \quad \mathcal{L}_V g + 2 \operatorname{Ric} + 2\lambda g = 0.$$

Here  $\operatorname{Ric}$  is the Ricci tensor field of  $g$  and  $\mathcal{L}_V$  is the Lie derivative with respect to  $V$ . Also, let  $Q$  be the  $(1, 1)$ -version of  $\operatorname{Ric}$ . For  $V$  a Killing or homothetical vector field we recover the Einstein manifolds while if  $\lambda$  is a constant then we call  $(V, \lambda)$  as being a *Ricci soliton*. In order to compute explicitly  $\mathcal{L}_V$  we add a technical condition regarding  $V$ , namely we suppose to be *torse-forming* (see [2]) which means that for any  $X \in \mathfrak{X}(M)$  we have for the Levi-Civita connection  $\nabla$ :

$$(3), \quad \nabla_X V = fX + \gamma(X)V$$

for a smooth function  $f \in C^\infty(M)$  and a 1-form  $\gamma \in \Omega^1(M)$ . Note that torse-forming vector fields appear in several areas of differential geometry and physics as is point out in [10]. From (3) it results:

$$(4) \quad \nabla_V V = [f + \gamma(V)]V,$$

which means that the endomorphism  $\nabla V$  has  $V$  as eigenvector with the eigenvalue  $f + \gamma(V)$ . Our main result is the following characterization of almost Ricci solitons in terms of scalar curvature.

**Proposition 1.** Let  $(M^{2n+1}, g, V, \lambda)$  be a torse-forming almost Ricci soliton such that  $V$  does not have zeros and  $n \geq 2$ . Let  $L_1$  be an  $n$ -plane orthogonal to  $V$  and  $L_2$  an  $(n + 1)$ -plane orthogonal to  $V$ . Then:

$$(5) \quad 2[\tau(L_1) - \tau(L_1^\perp)] = \lambda + f + \gamma(V), \quad 2[\tau(L_2) - \tau(L_2^\perp)] = -\lambda - f + \gamma(V).$$

Conversely, let  $(M^{2n+1}, g, V, f, \gamma)$  be a Riemannian manifold endowed with a torse-forming vector field without zeros and  $n \geq 2$ . Let  $\lambda \in C^\infty(M)$  such that the identities (5) hold and  $V$  is an eigenvalue of  $Q$  with the eigenfunction  $-\lambda - f - \gamma(V)$ . Then  $(M, g, V, \lambda)$  is an almost Ricci soliton.

**Proof** We follow the technique of [1]. Let  $\{e_1, \dots, e_n\}$  be an orthonormal basis of  $L$  and  $\{e_{n+1}, \dots, e_{2n}, e_{2n+1} = \frac{V}{\|V\|}\}$  an orthonormal basis on  $L^\perp$ . Also  $\operatorname{Ric}(X, X)$  will be

denoted  $\text{Ric}(X)$ . We have:

$$(6) \quad \begin{cases} \text{Ric}(e_1) = K(e_1 \wedge e_2) + \dots + K(e_1 \wedge e_{2n+1}) = -\lambda - g(\nabla_{e_1} V, e_1) = -\lambda - f, \\ \vdots \\ \text{Ric}(e_{2n}) = K(e_{2n} \wedge e_1) + \dots + K(e_{2n} \wedge e_{2n+1}) = -\lambda - g(\nabla_{e_{2n}} V, e_{2n}) = -\lambda - f, \\ \text{Ric}(e_{2n+1}) = K(e_{2n+1} \wedge e_1) + \dots + K(e_{2n+1} \wedge e_{2n}) = -\lambda - g(\nabla_{e_{2n+1}} V, e_{2n+1}), \end{cases}$$

$$\text{Ric}(e_{2n+1}) = -\lambda - f - \gamma(V).$$

By summing up the first  $n$  equation we get:

$$(7) \quad 2\tau(L_1) + \sum_{1 \leq n < j \leq 2n+1} K(e_i \wedge e_j) = -n(\lambda + f).$$

Also, by summing up the last  $(n + 1)$  equations we obtain:

$$(8) \quad 2\tau(L_1^\perp) + \sum_{1 \leq n < j \leq 2n+1} K(e_i \wedge e_j) = -(n + 1)(\lambda + f) - \gamma(V)$$

and the first claimed relation follows directly. With a similar argument we derive the second claimed identity.

To obtain the converse fix  $p \in M$  and  $u \in T_p M$  an arbitrary unit vector orthogonal to  $V(p)$ . Let  $\{e_1 = u, \dots, e_{2n}, e_{2n+1} = \frac{V}{\|V\|}(p)\}$  be an orthonormal basis of  $T_p M$  and consider  $L_1 = \text{span}\{e_2, \dots, e_{n+1}\}$  respectively  $L_2 = \text{span}\{e_1, \dots, e_{n+1}\}$ . Then  $L_1^\perp = \text{span}\{e_1, e_{n+2}, \dots, e_{2n+1}\}$  and  $L_2^\perp = \text{span}\{e_{n+2}, \dots, e_{2n+1}\}$ . We get:

$$\begin{aligned} \text{Ric}(u) &= [K(e_1 \wedge e_2) + \dots + K(e_1 \wedge e_{n+1})] + [K(e_1 \wedge e_{n+2}) + \dots + K(e_1 \wedge e_{2n+1})] \\ &= [\tau(L_2) - \sum_{2 \leq i < j \leq n+1} K(e_i \wedge e_j)] + [\tau(L_1^\perp) - \sum_{n+2 \leq i < j \leq 2n+1} K(e_i \wedge e_j)] \\ &= [\tau(L_2^\perp) - \tau(L_1) - \frac{1}{2}(\lambda + f - \gamma(V))] \\ &\quad + [\tau(L_1) - \tau(L_2^\perp) - \frac{1}{2}(\lambda + f + \gamma(V))] = -\lambda - f. \end{aligned}$$

From (3) we have:

$$\mathcal{L}_V g(u, u) = 2g(\nabla_u V, u) = 2f.$$

The last two relations yields:  $[\mathcal{L}_V g + 2 \text{Ric} + 2\lambda g]|_{V^\perp} = 0$ . From (4) and the hypothesis about  $Q$  we derive:

$$(\mathcal{L}_V g + 2 \text{Ric} + 2\lambda g)(V, V) = 0$$

and the proof is complete. □

**Example 1.**

- I)  $f := 1$ , i.e.,  $V$  is a *irrotational* vector field.
- II)  $f := 0$ , i.e.,  $V$  is a *recurrent* vector field.
- III) Let  $\eta$  be the 1-form dual of  $V$  with respect to  $g$ . If  $\gamma = \eta$  then  $\gamma(V) = \|V\|^2$ .
- IV) If  $V$  belongs to the annihilator of  $\gamma$  then  $V$  is called *torqued* and Ricci solitons of this type are studied in [4].
- V) If  $V$  is Killing then we recover a half part of Theorem 3.

**Open problem.** Let  $V$  be a fixed vector field on  $(M, g)$ . We call it *Ricci-sectional vector field* if for any 2-plane  $\pi$  the quantity:

$$K_V^{\text{Ric}}(u, v) := (\mathcal{L}_V g + 2 \text{Ric})(u, v)$$

does not depends on the basis  $\{u, v\}$  of  $\pi$ . Is an open problem to characterize and exemplify this class of vector fields and to connect this family with the theory of (almost) Ricci solitons.

**Acknowledgements.** The author thanks to the two referees for their valuable suggestions that definitely improved the paper.
