# NOTE ON GRAY CODES FOR PERMUTATION LISTS

## Seymour Lipschutz, Jie Gao, and Dianjun Wang

Communicated by Slobodan Simić

ABSTRACT. Robert Sedgewick [5] lists various Gray codes for the permutations in  $S_n$  including the classical algorithm by Johnson and Trotter. Here we give an algorithm which constructs many families of Gray codes for  $S_n$ , which closely follows the construction of the Binary Reflexive Gray Code for the *n*-cube  $Q_n$ .

### 1. Introduction

There are (n!)! ways to list the n! permutations in  $S_n$ . Some such permutation lists have been generated by a computer, and some such permutation lists are Gray codes (where successive permutations differ by a transposition). One such famous Gray code for  $S_n$  is by Johnson [4] and Trotter [6]. In fact, each new permutation in the Johnson–Trotter (JT) list for  $S_n$  is obtained from the preceding permutation by an adjacent transposition.

Sedgewick [5] gave a survey of various Gray codes for  $S_n$  in 1977. Subsequently, Conway, Sloane and Wilks [1] gave a new Gray code CSW for  $S_n$  in 1989 while proving the existence of Gray codes for the reflection groups. Recently, Gao and Wang [2] gave simple algorithms, each with an efficient implementation, for two new permutation lists  $GW_1$  and  $GW_2$  for  $S_n$ , where the second such list is a Gray code for  $S_n$ . The four lists, JT, CSW,  $GW_1$  and  $GW_2$ , for n = 4, are pictured in Figure 1.

This paper gives an algorithm for constructing many families of Gray codes for  $S_n$  which uses an idea from the construction of the Binary Reflected Gray Code (BRGC) of the *n*-cube  $Q_n$ .

Our paper is organized as follows. Section 2 describes the Binary Reflected Gray Code for  $Q_n$ , and also discusses the generation of the JT list and the CSW list for  $S_n$ . Section 3 gives our algorithm which constructs our new Gray code L(n) for  $S_n$ , and also constructs many families of Gray codes for  $S_n$ .

FIGURE 1. JT, CSW,  $GW_1$  and  $GW_2$  Lists for n = 4

## 2. Gray Codes and the JT and CSW lists

The original idea of a Gray code was to list the codewords (*n*-bit strings) in the *n*-cube  $Q_n$  so that successive codewords differ in only one bit. Thus a Gray code for  $Q_n$  is a Hamiltonian circuit through the 2n vertices of  $Q_n$ . [The fact that this can be done for any  $Q_n$  follows from the construction of the Binary Reflected Gray Code (*BRGC*) for  $Q_n$  (see [**3**]) which we describe below.]

The above idea of a Gray code has been generalized as follows. A Gray code for any combinatorial family of objects is a listing of the objects such that only a "small change" takes place from one object to the next in the list. The definition of "small change" depends on the particular family, its context, and its applications.

$Q_3$	$Q_3$ reversed	
01100110	00111100	
00001111	01100110	
00111100	$1\ 1\ 1\ 1\ 0\ 0\ 0\ 0$	
000000000	11111111	

FIGURE 2. Binary Reflected Gray Code for  $Q_4$ 

For example, for a finite group G with a set of generators, a Gray code for G is usually a Hamiltonian circuit in its Cayley graph or, equivalently, a listing of the elements of G so that successive elements differ by the product of a generator.

This paper is mainly interested in the following type of Gray code for  $S_n$ . [Other types of Gray codes for  $S_n$  also exist.]

DEFINITION 1. A Gray code for  $S_n$  is a list L of the elements in  $S_n$  such that successive permutations differ by a transposition.

We begin by describing a recursive construction of the Gray code for the *n*-cube  $Q_n$ . Specifically, Figure 2 shows how the *BRGC* for  $Q_4$  can be obtained from the *BRGC* for  $Q_3$ . That is, first we list the Gray code for  $Q_3$  which appears as the upper left  $3 \times 8$  matrix (where the codewords are the columns). Then next to it we list the Gray code for  $Q_3$  but in reverse order. This yields a  $3 \times 8$  matrix. Finally, we add a fourth row consisting of eight 0's followed by eight 1's. This gives the *BRGC* for  $Q_4$ .

We show that this is in fact a Gray code for  $Q_4$ . Observe that only one bit changes within the first eight columns since the fourth bit is always 0, and only one bit changes within the last eight columns since the fourth bit is always 1. Furthermore, the two middle columns (and also the first and last columns) are identical except for the added last bits, and so again only one bit changes. The *BRGC* for  $Q_n$  is the one obtained recursively in this way beginning with the matrix [0,1] for  $Q = Q_1$ . [Note this construction gives a Hamiltonian circuit, not just a Hamiltonian path, for the *n*-cube  $Q_n$ .]

Discussing the BRGC, Herbert Wilf [7] comments: "This method of copying a list and its reversal seems to be a good thing to think of when trying to construct some new kind of Gray code." We do this below in our main algorithm.

The Johnson-Trotter permutation list is also defined recursively. The list for n = 4 is shown in Figure 1. Note that the list is partitioned into six "blocks", each with four successive permutations. Each block corresponds and is labelled by a permutation in  $S_3$  which is in boldface and is to the right of the block. We note that the boldface labels form the JT list for  $S_3$ .

Now in the first block, the largest item 4 sweeps from right to left, in the second block from left to right, in the third block for right to left, and so on. Also, the relative positions of the remaining items 1, 2, 3 do not change in each block and correspond to the label of the block. Moreover, the recursive changes of the relative positions of 1, 2, 3 occur only from block to block when the largest item 4 is in an end position. Thus the item 4 does not interfere with any transposition involving

the items 1, 2, 3. Thus the Johnson–Trotter list JT(n) is a Gray code for  $S_n$ . [In fact, successive permutations in JT(n) differ by only an adjacent transposition.]

The Conway–Sloane–Wilks (CSW) list is also defined recursively. The second column in Figure 1 indicates how CSW(4) is obtained from CSW(3). First the number n = 4 is appended to each permutation in CSW(3) which appears in boldface in Column 2. Then a sequence of 3! = 6 permutations is inserted between each pair of permutations in CSW(3) which end in the same number, that is, between 123 and 213, between 231 and 321, and between 312 and 132. We refer the reader to their paper for a full description of their algorithm.

The last two columns in Figure 1 contain, respectively, the Gao–Wang permutation lists  $GW_1$  and  $GW_2$  for n = 4. Observe that each list is partitioned into four "blocks", where each block contains 6 successive permutations (which actually correspond to the 6 permutations in  $S_3$ ). We describe the construction of the list  $GW_1(n)$  here by showing how  $GW_1(4)$  is obtained from  $GW_1(3)$ . The first block in  $GW_1(4)$  contains, in boldface, the permutation list for  $GW_1(3)$  with each such permutation preceded by the number 4. The second block contains the same permutation list  $GW_1(3)$  but now the 4 is in the second position. And so on. The construction of the permutation list  $GW_2$  lies beyond the scope of this paper.

### **3.** Generating Algorithm and a New Gray Code L(n) for $S_n$

Here we give an algorithm which is used to generate a new Gray code L(n) for  $S_n$  and which can also be used to generate many other families of gray codes for  $S_n$ . First, however, we need some new notation and terminology. Let L be a list. We let  $L^R$  denote the list L written backwards, and we let r \* L denote the list consisting of r alternating copies of L and  $L^R$ ; that is:

$$r * L = [L; L^R; L; L^R; ...; L \text{ or } L^R] \quad (r \text{ components}).$$

Each copy of L or  $L^R$  will be called a block in r \* L. Note that r \* L ends in L or  $L^R$  according as r is odd or even.

Now let x be a letter. Note first that there are r + 1 places to add x to an r-letter word w. For example, if w = abcd, then there are 5 places to add x to the word w as follows:

### xabcd, axbcd, abxcd, abcxd, abcdx.

Next we define a new type of list. Let  $L = [B_1; B_2; \ldots; B_{r+1}]$  be a list of r-item words which is partitioned into r + 1 nonempty sublists  $B_i$  (called blocks), and let x be a letter. Then we define

to be the list obtained by "interweaving x block by block in L", that is, where x is added before the first item in every word in  $B_1$ , before the second item in every word in  $B_2$ , and so on, until x is added after the last item in every word in  $B_{r+1}$ .

For example, suppose L = [ab, a'b'; cd; ef, e'f'], a list of five r = 2 letter words partitioned into r + 1 = 3 blocks (separated by semicolons). Then

$$I[x,L] = [xab, xa'b'; cxd; efx, e'f'x].$$

The following algorithm applies.

**Algorithm 3.1.** The input is a permutation list L for  $S_{n-1}$ , where n > 2, and the output is a permutation list L' for  $S_n$ .

**Step 1**. Form the list n \* L which consists of n alternating copies of L and  $L^R$ . **Step 2**. Interweave the number n block by block in n\*L yielding L' = I[n, n\*L].

The fact that L' is a list of permutations of  $S_n$  follows from the fact that L' contains n! permutations and no two of them are the same.

We are now ready to define our permutation list L(n). Firstly, we let L(1) = [1]and L(2) = [21, 12]). Then, for n > 2, we let L(n) be obtained from L(n-1) using the above Algorithm 3.1. We illustrate how L(3) and L(4) are obtained below.

EXAMPLE 1. We apply Algorithm 3.1 to L(2) = [21, 12] to obtain L(3): Step 1. Form the list  $3 * L(2) = [L(2); L^R(2); L(2)]$ , that is,

$$3 * L(2) = [21, 12; 12, 21; 21, 12]$$

**Step 2**. Interweave 3 block by block in 3 \* L(2) yielding

L(3) = [321, 312, 132, 231, 213, 123]

EXAMPLE 2. We apply Algorithm 3.1 to L(3) to obtain L(4): Step 1. Form the list  $4 * L(3) = [L(3); L^R(3); L(3); L^R(3)]$ , that is,

4 \* L(3) = [321, 312, 132, 231, 213, 123; 123, 213, 132, 231, 312, 321;

321, 312, 132, 231, 213, 123; 123, 213, 132, 231, 312, 321

**Step 2.** Interweave 4 block by block in 4 \* L(3) yielding L(4) = I[4, 4 \* L(3)]. Namely:

L(4) = [4321, 4312, 4132, 4231, 4213, 4123; 1423, 2413, 1432, 2431, 3412, 3421;

3241, 3142, 1342, 2341, 2143, 1243; 1234, 2134, 1324, 2314, 3124, 3214

Observe that that L(4) has 4(6) = 24 permutations, as expected.

REMARK. Suppose in Algorithm 3.1 we change Step 1 so that we form the list  $L^n$ , *n* copies of *L*, not alternating *L* and  $L^R$ . Then, beginning with L(1) = 1 and successively applying the modified Algorithm 3.1, we would obtain the Gao-Wang List  $GW_1$  which is not a Gray code for  $S_n$ .

The importance of our Algorithm 3.1 comes from the following theorem.

MAIN THEOREM. Suppose L is a Gray code for  $S_{n-1}$ , and suppose L' is obtained from L using Algorithm 3.1. Then L' is a Gray code for  $S_n$ .

PROOF. Since L is a Gray code for  $S_{n-1}$ , we have that  $L^R$  is also a Gray code for  $S_{n-1}$ . Thus successive permutations within each block of L' = I[n, n \* L] differ only by a transposition since n is always in the same position and the remaining members of the list are in the same relative position as in L or  $L^R$ .

Now consider successive permutations from one block to the next in L'. Note that the last permutation in L is the same as the first permutation in  $L^R$ , and the last permutation in  $L^R$  is the same as the first permutation in L. Thus the only change from the last permutation in a block in L' to the first permutation in the

next block is that n interchanges its position with the next integer. Thus again successive permutations in L' differ only by a transposition.

Accordingly, L' is a Gray code for  $S_n$ , and the theorem is proved.

We now give applications of our Main Theorem.

EXAMPLE 3. (a) L(2) = [21, 12] is a Gray code for  $S_2$ . Therefore our lists L(n) are Gray codes for  $S_n$ .

(b) Consider an integer r > 1, the Johnson-Trotter Gray code JT(r) for  $S_r$ , and the Gao-Wang list  $GW_2(r)$  which is also a Gray code for  $S_r$ . Accordingly, applying Algorithm 3.1 successively to JT(r) or to GW(r) yields Gray codes for  $S_n$  for n > r.

The above example, which gives two families of Gray codes for almost all  $S_n$ , may indicate that the number of Gray codes for  $S_n$  which can be easily generated by a computer may be more numerous than some may have previously assumed.

Acknowlegement. The work reported here was done while the first author Prof. Seymour Lipschutz was visiting Tsinghua University. He is thankful to Tsinghua University for its hospitality.
